ACRI 2022 – Geneva, 13 September 2022

S-boxes in symmetric crypto

(a) Substitution-Permutation Network (SPN)

Zoom in on a **S-box** S_i :

$$\Downarrow F : \{0, 1\}^n \rightarrow \{0, 1\}^n$$

(b) S-box S_i

S-boxes in SPN ciphers must satisfy several properties, mainly:

- ▶ **invertibility** (for decryption)
- ▶ High **nonlinearity** (for resistance to linear cryptanalysis)

Cellular Automata

- ▶ One-dimensional **Cellular Automaton** (CA): a discrete parallel computation model composed of a finite array of n **cells**

Example: $n = 6$, $d = 3$, $f(s_i, s_{i+1}, s_{i+2}) = s_i \oplus s_{i+1} \oplus s_{i+2}$ (rule 150)

No Boundary CA – NBCA

Periodic Boundary CA – PBCA

- ▶ Each cell updates its **state** $s \in \{0, 1\}$ by evaluating a **local rule** $f : \{0, 1\}^d \rightarrow \{0, 1\}$ on itself and the $d - 1$ cells on its right

CA-based symmetric ciphers

The "**dynamical system**" way:

- ▶ Iterate a CA for **several** time steps to encrypt the **whole** plaintext
- ▶ Typically seen in CA venues [S04, M06, S08]
- ▶ Several weaknesses (low diffusion, ...)

The "**reductionist**" way:

- ▶ Iterate a CA for a **single** time step to encrypt a **part** of plaintext
- ▶ More common in crypto venues [P17, G18, M19]
- ▶ In line with current state of the art

Real world CA-Based Crypto: Keccak χ S-box

- ▶ Local rule: $\chi(x_1, x_2, x_3) = x_1 \oplus (1 \oplus (x_2 \cdot x_3))$ (rule 210)
- ▶ Invertible for every odd size n of the CA

- ▶ Used as an S-box with $n = 5$ in the Keccak specification of the SHA-3 standard [B11]

Periodic CA-based S-boxes

Algebraic approach:

- ▶ Theoretical analysis of specific CA rules as S-boxes
- ▶ Examples: χ in Keccak [B11]

Heuristic approach:

- ▶ Use of heuristic algorithms (e.g. GP) to optimize the crypto properties of CA rules [P17, M19]
- ▶ More flexibility wrt other properties (e.g. implementation cost)

Another angle: Orthogonal Latin Squares (OLS)

Definition

A *Latin square* is a $n \times n$ matrix where all rows and columns are permutations of $[n] = \{1, \dots, n\}$. Two Latin squares are *orthogonal* if their superposition yields all the pairs $(x, y) \in [n] \times [n]$.

| | | | |
|---|---|---|---|
| 1 | 3 | 4 | 2 |
| 4 | 2 | 1 | 3 |
| 2 | 4 | 3 | 1 |
| 3 | 1 | 2 | 4 |

| | | | |
|---|---|---|---|
| 1 | 4 | 2 | 3 |
| 3 | 2 | 4 | 1 |
| 4 | 1 | 3 | 2 |
| 2 | 3 | 1 | 4 |

| | | | |
|---|---|---|---|
| 1 | 3 | 4 | 2 |
| 4 | 2 | 1 | 3 |
| 2 | 4 | 3 | 1 |
| 3 | 1 | 2 | 4 |

Remark: two OLS define a **bijection** over pairs in $[n] \times [n]$

Latin Squares through Bipermutive CA (1/2)

- ▶ **Bipermutive CA**: denoting $\mathbb{F}_2 = \{0, 1\}$, local rule f is defined as

$$f(x_1, \dots, x_d) = x_1 \oplus \varphi(x_2, \dots, x_{d-1}) \oplus x_d$$

- ▶ $\varphi : \mathbb{F}_2^{d-2} \rightarrow \mathbb{F}_2$: **generating function** of f

Lemma ([M20])

A CA $F : \mathbb{F}_2^{2(d-1)} \rightarrow \mathbb{F}_2^d$ with bipermutive rule $f : \mathbb{F}_2^d \rightarrow \mathbb{F}_2$ generates a Latin square of order $N = 2^{d-1}$

Latin Squares through Bipermutive CA (2/2)

- ▶ **Example:** CA $F : \mathbb{F}_2^4 \rightarrow \mathbb{F}_2^2$, $f(x_1, x_2, x_3) = x_1 \oplus x_2 \oplus x_3$ (Rule 150)
- ▶ Encoding: $00 \mapsto 1, 10 \mapsto 2, 01 \mapsto 3, 11 \mapsto 4$

(a) Rule 150 on 4 bits

| | | | |
|---|---|---|---|
| 1 | 4 | 3 | 2 |
| 2 | 3 | 4 | 1 |
| 4 | 1 | 2 | 3 |
| 3 | 2 | 1 | 4 |

(b) Latin square L_{150}

Orthogonal Cellular Automata (OCA): two bipermutive CA F, G generating a pair of OLS

Linear OCA

- ▶ **Bipermutive Linear rule:** $f(x) = x_1 \oplus a_2 x_2 \oplus \dots \oplus a_{d-1} x_{d-1} \oplus x_d$
- ▶ **Polynomial rule:** $P_f(X) = 1 + a_2 X + \dots + a_{d-1} X^{d-2} + X^{d-1}$

Theorem ([M20])

Two bipermutive linear rules generates OCA if and only if their associated polynomials are coprime

| | | | |
|---|---|---|---|
| 1 | 4 | 3 | 2 |
| 2 | 3 | 4 | 1 |
| 4 | 1 | 2 | 3 |
| 3 | 2 | 1 | 4 |

(a) Rule 150

| | | | |
|---|---|---|---|
| 1 | 2 | 3 | 4 |
| 2 | 1 | 4 | 3 |
| 3 | 4 | 1 | 2 |
| 4 | 3 | 2 | 1 |

(b) Rule 90

| | | | |
|---|---|---|---|
| 1 | 4 | 3 | 2 |
| 1 | 2 | 3 | 4 |
| 2 | 3 | 4 | 1 |
| 2 | 1 | 4 | 3 |
| 4 | 1 | 2 | 3 |
| 4 | 3 | 4 | 1 |
| 3 | 2 | 1 | 2 |
| 3 | 4 | 2 | 1 |

(c) Superposition

Figure: $P_{150}(X) = 1 + X + X^2$, $P_{90}(X) = 1 + X^2$ (coprime)

S-boxes based on OCA

Basic Idea:

- ▶ Evaluate two OCA F, G over the input $x = (x_L, x_R)$
- ▶ Use the outputs $F(x_L, x_R)$ and $G(x_L, x_R)$ as left and right outputs of a S-box H

Motivation:

- ▶ The S-box is **invertible** (because of orthogonality)
- ▶ Latin squares ensure a minimum degree of **diffusion**
- ▶ Approach used iteratively in [M21] to generate pseudorandom sequences

Search for nonlinear OCA S-boxes

- ▶ **Method:** exhaustive search of OCA pairs of $d = 4, 5$, which generate S-boxes of $n = 6, 8$ bits
- ▶ Compute the **nonlinearity** of the S-boxes as the **minimum nonlinearity** of their component functions

The diagram illustrates the mapping from input bits to component functions. At the top, a row of eight boxes contains the input bits $x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8$. Below this row, a downward arrow is labeled $F: \mathbb{F}_2^n \rightarrow \mathbb{F}_2^m$. Underneath the arrow is another row of eight boxes containing the component functions $f_1, f_2, f_3, f_4, f_5, f_6, f_7, f_8$. Three arrows point from the boxes f_1, f_3, f_5 down to the expression $(0, 1, 0, 1, 0, 1, 0, 0) \cdot F = f_1 \oplus f_3 \oplus f_5$.

- ▶ Nonlinearity of a component $v \cdot F$: computed with the **Walsh-Hadamard transform**

Result: All S-boxes are linear! :-)

- ▶ **First finding:** all tested S-boxes are linear
- ▶ Linear components form a **vector subspace** of $\{0, 1\}^n$

Table: Classification of OCA-based S-boxes of diameter $d = 4$ and $d = 5$ in terms of the nonlinearity of their local rules and LCS dimensions.

| d | $nl(f, g)$ | $\#OCA$ | dim | $\#dim$ |
|-----|------------|---------|-------|---------|
| 4 | (4,4) | 32 | 3 | 32 |
| | (4,4) | 768 | 4 | 768 |
| 5 | (8,8) | 768 | 4 | 704 |
| | (8,8) | | 3 | 64 |

- ▶ **Consequence:** useless as S-boxes :-)

The structure of LCS vector spaces

- ▶ Vector spaces over finite fields are **error-correcting codes**
- ▶ What about the **generating matrices** of LCS in OCA?

$$G = \begin{pmatrix} a_0 & \cdots & a_{t-1} & 1 & 0 & \cdots & \cdots & \cdots & \cdots & 0 \\ 0 & a_0 & \cdots & a_{t-1} & 1 & 0 & \cdots & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & \cdots & \cdots & \cdots & 0 & a_0 & \cdots & a_{t-1} & 1 \end{pmatrix}.$$

- ▶ ... but this is the form of the transition matrix of a linear CA!
- ▶ So: *the subspaces of the linear components of OCA S-boxes are represented themselves by a linear CA*

Summing up:

- ▶ OCA cannot be used to design useful S-boxes
- ▶ Surprisingly, the vector space of the linear components of an OCA S-box is *itself* a linear CA

Future directions:

- ▶ Check if there are nonlinear OCA S-boxes of higher diameter
- ▶ If not, can the CA structure of LCS be used to give a theoretical characterization of nonlinear OCA?
